QA RETEST SUMMARY REPORT

HandyMen App - Backend API Testing (Postman/Newman)
QA RETEST Report - Prepared for Development Team Review
By Oche Akor

Detail	Information
Project	HandyMen App API Retesting - Functional, Negative, Edge, Contract, and Security Testing
Environment Tested	https://staging.api.onyapay.com/api/v1/handyman/swagger-ui/index.html#/
Scope	144 Logged defects across 57 endpoint paths and 11 modules
Test Cases Executed	144 (Negative / Edge)
Method	Postman + Newman automated API execution, manual retest reconciliation, Excel defect log highlight.
Report Date	July 17, 2026
Prepared By	Oche Akor, QA Engineer

1. Retest Summary

This report presents the API retest results for the previously logged defects captured on the API endpoints for HandyMen App. After the first test run on 332 test cases, 144 defects were logged across several severity levels, critical, high, low. The failed test cases occurred mostly when the system was tested with Negative and Edge scenarios that an Engineer might not think about, to strengthen and tighten the systems security. The retest was done using Newman in the CLI and then all 144 were manually tested in postman to arrive at the final result. The result is available in the attached Defect log Excel spreadsheet.

The aggregated source of truth shows 144 retest cases, with 94 now closed and 50 still open. The resulting pass rate on the retest is 65.28%. Bringing the total number of passes test cases on the original file to 282 with 50 unresolved defects still open.

Although, 50 failed cases still remain open, the major critical release blockers previously reported have been significantly handled, only two cases with critical severity flags are still open. The bulk of the 50 open cases steam from the other two major causes pinpointed in the previous report, viz-a-viz, bad exception and error handling rules, getting a 400 bad request where a 401 unauthorized and also some cases where 401 unauthorized were expected but received HTTP 200, meaning requests without valid authorization appear to be processed (TC-012, TC-013)

The defect log (attached Excel Workbook) contains 144 active defects: 90 closed, 50 open.

2. Metrics

Metric	Value
Total Test Cases	144
Closed	90
Open	50
Not Run	0
Pass Rate	65.28%
High Priority Open Defects	2

3. Recommendations

- Lead development triage with the remaining 50 open cases.
- Use the defect categorization in the entry summary above and workbook rows as supporting evidence rather than creating many separate root-cause narratives for the same issue.
- Keep error handling and exception functions/classes custom and rules based rather than a generic one size fits all solution to wrong user.

- After fixes are deployed, rerun those specific test cases in the collection in postman and refresh the workbook before release-readiness sign-off.

12. Conclusion

On retest, the HandyMen API is thoroughly tested and improved with tighter security enough for an initial launch. It was rigorously tested with every know security scenario that could have been exploited. test evidence is internally consistent: a new total of 282 of 332 tests pass, with only 50 fails, the defect log now contains only few active defects, from the Newman auto test records 144 assertion failures. The API shows good defensive validation in almost all areas, but the remaining critical authorization bypass patterns should be fixed and retested before release approval.
